

MEDICAL IMAGE PROCESSING METHOD
AND MEDICAL IMAGE PROCESSING APPARATUS

5

BACKGROUND OF THE INVENTION

Field of the Invention

The present invention relates to medical image processing method and apparatus for processing a medical image

10 photographed by using radiation, etc.

Description of a Related Art

Photography using radiation (X-ray, α -ray, β -ray, γ -ray, electron beam, ultraviolet ray and so on) is conventionally
15 utilized in various fields, and is one of most important means for a diagnosis particularly in a medical field. An X-ray radiography is variously improved since the realization of a first X-ray radiograph, and a method using combination of a fluorescent screen and an X-ray film is a main current at
20 present. In recent years, various digitalized devices such as an X-ray CT, an ultrasonic diagnosis and an MRI are practically used in a medical image diagnosis, and construction of diagnostic information processing systems, etc. within hospitals is going to be advanced. Many researches
25 for the digitalization have been also made with respect to an

0000777 * 11101
X-ray image, and radiography using photostimulable phosphor is established and is practically used as a method to replace the conventional X-ray radiography.

Photostimulable phosphor (accumulative phosphor) is such substance that accumulates a part of radiation energy when irradiated with radiation and then generates photostimulated luminescence light in accordance with the accumulated energy when irradiated with excitation light such as a visible ray. Existence of the photostimulable phosphor was conventionally known. Radiography using the photostimulable phosphor is constructed as follows. That is, a radiation image of an object such as a human body is photographed and recorded on a sheet coated with the photostimulable phosphor. When the photostimulable phosphor sheet is scanned by excitation light such as a laser beam, photostimulated luminescence light is generated so that image data is obtained by photo-electrically reading the light. After the image data is suitably processed, an image represented by the image data is displayed on a display such as a CRT, or is printed on a film by a laser printer, etc. so that the radiation image can be displayed as a visible image.

Such radiography has performance equivalent to the conventional X-ray radiography in view of photographing sensitivity and image quality. For example, in comparison with the conventional X-ray radiography, an exposure area is very wide and a response of the photostimulated luminescence

light to an exposure amount is approximately proportional to the exposure amount over the entire exposure area. Therefore, even when the object is photographed in any radiation amount, a luminescence area where the image exists can be grasped and

5 normalized to be converted to a digital signal without under or over amounts. By combining the obtained signal with a suitable image processing method, an image of high quality can be steadily provided even under various kinds of photography condition. Further, since the obtained image is stored as

10 image data, a large amount of image data can be stored for a long time period without causing deterioration of the image, and developments to a medical diagnostic information system, etc. can be realized.

Fig. 8 shows an example of a radiation image reading

15 apparatus and a radiation image processing apparatus using the photostimulable phosphor sheet. A photostimulable phosphor sheet 31, on which a radiation image is recorded, is set to a predetermined position of the reading apparatus. The photostimulable phosphor sheet 31 is conveyed in Y-direction

20 by a sheet conveying means 33 driven by a motor 32. On the other hand, a light beam (excitation light) 35 generated from a laser light source 34 is reflected and deflected by a rotary polygon mirror 37, which is driven by a motor 36 and rotated at high speed in an arrow direction, and passes through a

25 convergent lens 38. Thereafter, an optical path of the light

beam 35 is changed by a mirror 39, and the photostimulable phosphor sheet 31 is scanned by the light beam 35 in X-direction. By the scanning, photostimulated luminescence light 40 is generated from a part of the photostimulable phosphor sheet 31 irradiated by the light beam 35. A light amount of the photostimulated luminescence light 40 corresponds to radiation image information accumulated and recorded on the sheet. The photostimulated luminescence light 40 is guided by an optical guide 41, and is photo-electrically detected by a photomultiplier (multiplier phototube) 42. An analog signal output from the photomultiplier 42 is amplified by an amplifier 43, and is digitized by an A/D converter 44. The digital signal is transmitted as image data to an image processing apparatus 45.

In such a process of reading photostimulated luminescence light, there is also a case where "pre-reading" of the data is executed. The "pre-reading" is executed by scanning the photostimulable phosphor sheet 31 in advance by light beam at a low level to read an image recorded on the sheet schematically so that image data obtained by the pre-reading is analyzed. Thereafter, "main reading" is executed by irradiating a light beam at a level higher than that of the light beam irradiated in the pre-reading and scanning the sheet to read the image data in optimal reading condition according to a dosage of the irradiated radiation, etc..

an arrangement of recording four pictures on one film and so on. In particular, in a case where it is desired to compare left-hand image with right-hand image as in mammography (breasts) or in a case where it is desired to observe front image and side image in parallel with each other as in the entire spine, a plurality of pictures are often displayed on one film, which will be called as a "multi-format output" hereinafter.

However, according to a conventional multi-format output, a plurality of pictures are output in a uniform format irrespective of kinds of the pictures. Therefore, clearances are formed between the plurality of pictures, which makes it difficult to compare the plurality of pictures with each other and to understand relation between the plurality of pictures.

Japanese patent application laid-open JP-A-3-287248 discloses a scoliosis diagnostic system for photo-electrically reading a radiation image of the spine recorded on the photostimulable phosphor sheet having a recording area corresponding to an entire length of the spine as an object to be photographed, executing image processing to reduce the read radiation image and outputting the reduced radiation image.

Further, Japanese patent application laid-open JP-A-8-294479 discloses a computer-supported image diagnostic apparatus. In the apparatus, an entire radiation image of an object is displayed, while local image data representing an

image in a local area including a detected abnormal shading candidate is extracted from the entire image data. The image in the local area is displayed separately from the entire image on the basis of the local image data. The above-mentioned

5 JP-A-8-294479 also discloses the following contents. In the case where X-ray images of breasts, etc. are to be displayed, an entire image of one breast and an entire image of the other breast are displayed simultaneously and adjacently back to back, for example. The local area including the abnormal

10 shading candidate detected from the entire image data of the one breast, and a local area with respect to the same portion of the other breast are displayed in window areas arranged on the screen displaying the respective entire images so that corresponding portions of both two breasts can be directly

15 compared and observed.

Further, Japanese patent application laid-open JP-A-9-238933 discloses a breast image display apparatus. In the case where pair images constructed by arranging a pair of left-hand and right-hand breast images back to back are

20 displayed, the breast image display apparatus displays the selected one of a vertical direction pair image obtained by photographing the pair of left-hand and right-hand breasts from a vertical direction, a side direction pair image obtained by photographing the pair of breasts from a side direction,

25 and a pair image with a local enlarged image partially including

09987377 a 1111109

a local area enlarged image obtained by enlarging the local area including the abnormal shading candidate within the vertical direction pair image and the side direction pair image so as to improve observation and photograph reading

5 performance.

However, at the actual scene of medical diagnosis, images are processed with respect to various objects by using the same apparatus. Therefore, it has been necessary for a user to select a format which conforms to each of the images every time

10 when a portion of an object to be photographed such as the entire spine or the mammography is changed.

SUMMARY OF THE INVENTION

The present invention was accomplished in view of such

15 problems. Accordingly, an object of the present invention is to provide an image processing method and an apparatus having control means able to change an output-format in accordance with the photographing condition.

To solve the above problems, a medical image processing

20 method, according to the present invention, of processing image data representing an image obtained by radiography and read by an image reading apparatus comprises the steps of: receiving the image data and photographing condition when the image is obtained; executing image processing of the image

25 data; reading output-format control information corresponding

to the photographing condition from a predetermined set of
output-format control information to be used to control an
image format when the image is output on a film; and
constructing layout of the image to be output on the basis of
5 the read output-format control information.

A medical image processing apparatus, according to the
present invention, for processing image data representing an
image obtained by radiography and read by an image reading
apparatus comprises: means for receiving the image data and
10 photographing condition when the image is obtained; means for
executing image processing of the image data; and means for
reading output-format control information corresponding to
the photographing condition from a predetermined set of
output-format control information to be used to control an
15 image format when the image is output on a film.

In the present invention, since the image is constructed
in accordance with the output-format which is set on the basis
of the photographing condition, each image can be output on
films in the optimal format for respective one of medical
20 diagnoses.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a view showing the construction of a system
including a medical image processing apparatus according to
25 one embodiment of the present invention;

Fig. 2 is a flow chart showing a medical image processing method according to a first embodiment of the present invention;

25 DESCRIPTION OF THE PREFERRED EMBODIMENTS

Embodiments of the present invention will now be described in detail with reference to the drawings. The same constituent elements are designated by the same reference numerals and explanation thereof will be omitted.

5 Fig. 1 is a view showing construction of a medical image processing system including a medical image processing apparatus according to one embodiment of the present invention. In the embodiment, a recording sheet used in radiography is coated with photostimulable phosphor substance and records
10 information of an object by being irradiated with radiation.

 The recording sheet (photostimulable phosphor sheet) 1, on which a radiation image is recorded by the radiography, is set to a predetermined position of a reading unit 10. A light beam generated from a laser light source 2 passes through an
15 optical scanning part 3 to scan a surface of the recording sheet 1. By this scanning, the recording sheet 1 is irradiated with excitation light and an amount of photostimulated luminescence light according to accumulated and recorded radiation image information is generated from the irradiated part. The
20 photostimulated luminescence light is photo-electrically detected by a photomultiplier (multiplier phototube) 4, and is output as an analog signal. The analog signal is amplified by an amplifier 5 and is digitized by an A/D converter 6. The digital signal is transmitted as image data to a processing
25 section 20.

In the processing section 20, a central processing unit (hereinafter called as CPU) 11 is connected to each unit through a system bus SB or a video bus VB. The processing section 20 includes an internal memory 12, a hard disk 13 as a recording medium for recording programs and databases to be used for operation of the CPU 11, and a hard disk control unit 14. Further, an input unit 21 such as a keyboard or a mouse for inputting instructions or information, a display unit 25 including a display 22 such as a CRT for displaying a visible image on the basis of image data and a printer 23 for printing the visible image are connected to the CPU 11 through an interface 15. Further, a floppy disk, an externally attached hard disk, MO, MT, RAM, CD-ROM, DVD-ROM and so on can be also used as a recording medium in addition to the built-in hard disk. It is also considered that an external device connected through a network is used as an output destination of the visible image or the image data. In this case, signals are transmitted and received through an external interface 17 between the external device and the CPU 11.

An operation of the CPU 11 will be explained. Image data output from the reading unit 10 is transmitted to the CPU 11 through a network interface 16. An image processing unit 11a executes image processing such as normalization, gradation processing or logic reading processing. On the other hand, when photographing condition is input from the input unit 21

to the CPU 11 through the interface 15, an output-format control information reading unit 11b reads output-format control information corresponding to the received photographing condition from the hard disk 13. An image constructing unit
5 11c constructs layout of the image data subjected to the above-mentioned image processing on the basis of the read output-format control information. A constructed picture is output to the display 22 or the printer 23 through the interface 15.

10 In this embodiment, each of the image processing unit 11a, the output-format control information reading unit 11b, the image constructing unit 11c and the output unit 11d as shown in Fig. 1 is constructed by the CPU which operates on the basis of a program, but can be also constructed by a digital circuit
15 or an analog circuit. Further, the output-format control information may be recorded on a recording medium such as a hard disk, a floppy disk, MO, MT, RAM, CD-ROM, or DVD-ROM.

Next, a medical image processing method according to a first embodiment of the present invention will be explained.
20 Fig. 2 is a flow chart showing the medical image processing method according to the first embodiment of the present invention.

At step S1, a user selects and registers a portion to be photographed, for example, "mammography" or "entire spine" in
25 accordance with a photography menu. A case of the mammography

will be explained below.

In the case of photographing the mammography, a total of four photographs are generally taken in which one photograph is taken from an inside slanting upside and the other photograph is taken from just above with respect to each of left-hand and right-hand breasts. Figs. 3A to 3D typically show relation of an object 100 seen from a front face in photography of the mammography and a recording sheet 30 and an irradiating direction of radiation. In Fig. 3A, the right-hand breast is photographed from the inside slanting upside, and an image as shown by an oblique line portion of a picture 30a is recorded on the recording sheet 30 irradiated by the radiation in an arrow direction. Also, the right-hand breast is photographed from just above in Fig. 3B, the left-hand breast is photographed from just above in Fig. 3C, and the left-hand breast is photographed from the inside slanting upside in Fig. 3D. Images of the object 100 as shown by oblique line portions of respective pictures 30b to 30d in Figs. 3B to 3D are recorded on the recording sheets 30 irradiated by the radiation in respective directions.

When the menu of the mammography is registered, four kinds of photographing condition as shown in Figs. 3A to 3D are registered at step S2. As to the photographing condition, there are detailed contents of portions to be photographed, irradiating directions of the radiation (photographing

directions) and so on as shown in Fig. 4.

At step S3, an image data and photographing condition under which the image is obtained are input. At step S4, image processing such as normalization, gradation processing or
5 logic reading processing is executed for the image data on the basis of respective image processing condition set in accordance with the photographing condition.

At step S5, output-format control information is obtained on the basis of the registered photographing condition for each
10 image data set. As the output-format control information, "inversion", "output position", "output size" and so on can be also included in addition to "rotation" or "position adjustment" as shown in Fig. 4. Further, the output-format control information may also include such information as
15 "two-picture construction with no clearance between first and second pictures". Such output-format control information is stored in advance in a database in correspondence with the photographing condition. Further, one kind of the output-format control information or a combination of plural kinds
20 of the output-format control information is set for each photographing condition.

At step S6, an output image of each image data set is constructed on the basis of the obtained output-format control information. Referring to Figs. 3A to 3D again, such
25 processing as "determination of the output position of an

image", "rotation" or "position adjustment" is executed with respect to the image data set constituting the pictures 30a to 30d, on the basis of the output-format control information corresponding to the photographing condition as shown in Fig.

- 5 4. Then, the output image as shown in Fig. 5A is constructed. For comparison, an image constructed in an original output-format is shown in Fig. 5B.

At this time, the user may make a preview of the above-mentioned output image to be displayed on the display.

- 10 Also, the user may adjust the picture while seeing the preview picture. Thereafter, at step S7, the constructed image is output on a film, etc. by a printer and a desirable visible image is obtained.

Thus, according to this embodiment, each image can be
15 output on the film in an optimal output-format set for that image in accordance with the photographing condition.

A medical image processing method according to a second embodiment of the present invention will next be explained.

- Fig. 6 is a flow chart showing the medical image processing
20 method according to the second embodiment of the present invention. This embodiment can be applied in a case where an external device for outputting the visible image has a function of constructing the output image on the basis of image attendant information.

- 25 Similar to the medical image processing method according

to the first embodiment of the present invention, when the user registers the photography menu at step S1, one or plural kind of photographing condition is registered in accordance with a portion to be photographed registered in the menu at step S2. At step S3, image data and the photographing condition under which the image is obtained are input. At step S4, image processing is executed with respect to the image data on the basis of image processing condition set in accordance with the photographing condition. At step S5, output-format control information is obtained for each image data set on the basis of the photographing condition.

At step S11, the obtained output-format control information is stored as attendant information of the image together with other attendant information (for example, a name of a patient, a photographing place, etc.). At step S12, the processed image data and the image attendant information are output to the external device connected through the external interface 17 (see Fig. 1). At step S13, the external device, which has received the data, constructs an output image of a visible image on the basis of the image attendant information. Subsequently, at step S14, the constructed image is output on a film, etc., then the user can obtain a desirable visible image.

According to this embodiment, since the image data and
25 the image attendant information are output as data itself, the

information is obtained on the basis of the photographing condition for each image data set.

At step S21, the obtained output-format control information is stored as image attendant information together
5 with the image data set. When a visible image is output, a user can give instruction as to whether the visible image is output which has been constructed on the basis of the image attendant information as shown in Fig. 5A or the visible image is output in the original output-format as shown in Fig. 5B.
10 Further, at this time, the user can also adjust the picture while seeing a preview picture. Thereafter, at step S22, the user can obtain a desirable visible image by instructing to output the visible image.

According to this embodiment, since the output image is
15 constructed by the user's instruction, each user can obtain the desirable visible image even when there are a plurality of plural users.

As mentioned above, according to the present invention, it becomes possible to provide visible images output in
20 respective optimal formats for respective medical diagnoses by obtaining information from among a predetermined information set for controlling an output-format on the basis of the photographing condition and constructing the visible images. Further, a medical image processing apparatus can be
25 provided which outputs such visible images.
